#### Abstract

Present study in the paper is concerned with the development of new genetic operators to optimize the performance of the system. To improve the production facilities, a set of jobs are executed on the set of machines. For better performance there are large numbers of constraints. Process scheduling theory has been developed to meet all side constraints. Process Schedule is done in such a way that the resulting solution minimizes the given objective function. Many variants of the basic scheduling problem can be formulated by differentiating between machine environments, side constraints and objective functions. Genetic algorithm have been applied to OSPSP. The study shows that proposed operators shows better results

Keywords- Genetic Algorithm,OSPSP,Operators,Scheduling.

## 1. INTRODUCTION

Process scheduling in an operating system can be stated as, "Selection of Process for Execution and allocation of the CPU to the selected process". Scheduling is considered as the fundamental function of OS. Efficient scheduling always increases the performance of the operating system. Scheduling is important because it influences user service and efficiency of processor. Therefore, the throughput and efficiency of the OS increases by use of efficient process scheduling.

## 2. SCHEDULING PROBLEMS

In OS the problem is to allocate available resources to the given process within desirable time period to perform a set of works. Realistic scheduling problem is very difficult to solve in OS. This is because it has many constraints. Some of the constraints cannot be defined mathematically.

In general scheduling problems can be production and computational fields. These are most important fields as related to scheduling. Different tasks individually compete for resources like manpower, money, processors (machines), energy and tools. These resources very differently in nature. Moreover, a organize set of tasks, reflecting relations among them can be defined in several ways. In addition, various criteria which measure the quality of the performance of a set of tasks can be taken into account.
[1] They characterized scheduling problems by three sets:
(i) set $\mathcal{J}=\{J 1, J 2, J 3 \ldots . J n\}$ of $n j o b s$,
(ii) set $\mathbb{P}=\{\mathrm{P} 1, P 2, \ldots, P m\}$ of $m$ processors (machines) and
(iii) set $\mathcal{R}=\{R 1, R 2 \ldots R s\}$ of $s$ types of additional resources $R$,

Process Scheduling means to assign Processors ( $P$ ) and Resources ( $\mathbb{R}$ ) to Tasks ( $\mathcal{T}$ ) in order to complete all tasks under the imposed constraints.

## 3. TYPES OF OPERATING SYSTEM SCHEDULERS

Operating systems generally have three types of distinct scheduler, "Long Term Scheduler","Medium Term Scheduler" and "Short Term Scheduler". These are based on the relative frequency with which these functions are performed. In OS the Scheduler module is responsible for selecting the next jobs to be admitted into the system and the next process to run.

### 3.1 Long Term Scheduler:

[2] The long term or admission scheduler decides which jobs or processes are to be admitted to the ready queue in the Main Memory It means that, when an attempt is made to execute a program, its admission to the set of currently executing processes is either authorized or delayed by the long term scheduler. Thus, this scheduler dictates what processes are to run on a system, In current operating systems, this is used to make sure that real time system CPU have more time to finish the particular task. So there is requirement for efficient real time scheduling for the modern system with GUI interface. Basically the queue is resided in the hard disk or in the virtual memory. Long term scheduling is also important in large scale systems like batch processing systems, computer clusters, and supercomputers and renders farms. In these regard dedicated job scheduler is required for this function

### 3.2 Medium Term Scheduler:

[2], The medium term scheduler removes processes from main memory. It places them on secondary memory like disk drive or other source of secondary memory or vice versa. In this process swapping of processes is takes place. The
medium term scheduler decides to swap out a process which has not been active for some time, or a process which has a low priority or a process which is taking up a huge amount of conventional memory in order to free up main memory, so that it can used for other processes.

### 3.3 Short Term Scheduler:

[2],CPU scheduler is the short term scheduler, It decides which of the ready processes are to be executed next following a clock interrupt, an I/O interrupt, an operating system call or another form of signal. The short term scheduler takes scheduling decision very quickly as compared to the long term scheduler. This scheduler can be preemptive. It implies that it is capable to remove processes forcibly from a CPU when it decides to allocate that CPU to another process, or non preemptive i.e when scheduler are not able to take off the control of CPU from the currently executed process.

### 3.4 IMPORTANCE OF SCHEDULING

Scheduling is a decision making practice. It is used in different types of operating system. Its aim is to optimize one or more objectives with the allocation of resources to tasks over given time periods. The resources and tasks in an organization can take a lot of different forms. The resources may be machines in a workshop, crews at a construction site, processing units in a computing environment, and runways at an airport and so on. The tasks may be operations in a production process, take offs and landings at an airport, executions of computer programs, stages in a construction project. Each task can have a definite priority level, an earliest likely starting time and a due date. The objectives can also take many different forms and one objective may be the minimization of the completion time of the last job and another may be the minimization of the number of jobs completed after their respective due dates. Scheduling plays an important role in most manufacturing and service systems as well as in most information processing environments.
Scheduling derives its importance from the two different considerations:
(i) Ineffective scheduling results in deprived utilization of available resources. A noticeable
symptom is the idleness of facilities, human resources and apparatus waiting for orders to be
processed. As a result of this cost of production increases.
(ii) Poor scheduling in the OS will always result in the increases of Average waiting time,
Turnaround Time and poor service response time. With ineffective scheduling the

Performance of the OS always reduced.

## 4. GENETIC ALGORITHM

Genetic Algorithms (GAs) are adaptive methods which may be used to solve search and optimization problems. They are based on the genetic processes of biological organisms. Over many generations, natural populations evolve according to the principles of natural selection and survival of the Fittest", First clearly stated by Charles Darwin in The Origin of Species. By mimicking this process, genetic algorithms are
able to evolve" solutions to real world problems, if they have been suitably encoded. For example, GAs can be used to design bridge structures, for maximum strength/weight ratio, or to determine the least wasteful layout for cutting shapes from cloth. They can also be used for online process control, such as in a chemical plant, or load balancing on a multiprocessor computer system. The basic principles of GAs were first laid down rigorously by Holland [3], and are well described in many texts (e.g. [4], [5],[6]). GAs simulates those processes in natural populations which are essential to evolution. Exactly which biological processes are essential for evolution, and which processes have little or no role to play is still a matter for research.

Due to the adaptability of the GA it can be used to solve complex problem. Scheduling problem is considered as the NP- Hard problem. GA is suitable to apply on scheduling problem for find out optimal solution.

## 5. METHODOLOGY FOR OSPSP

In the present work GA have been proposed as a Long Term Scheduler (LTS).GA is a robust search technique. It has the capability to cope with problem on which it is applied. So GA can enhance the performance of the OS. Survey of literature shows that GA has been applied to scheduling problem of different domains. They have applied GA to the scheduling problem with prevailing data mining of parameter setting. The present data mining is used to the optimal parameter setting of GA under the given scheduling problem. Thus, it is proposed to use parameter setting of GA under the permutation encoding. The best parameter setting under OSPSP with permutation encoding has given better results.
During the research work, it was found that permutation encoding to represent the candidate solution gives optimal parameter setting for OSPSP. Thus, there was a need to analyze the parameter setting of GA based on permutation encoding under the scheduling problems. To develop new algorithm, it became essential to analyze the parameter setting for permutation encoding.

From the survey of literature, it was observed that permutation encoded genetic operators are very limited. There is a need to design new genetic operator. The new genetic operator should be based on permutation encoding. Research was carried out to find new genetic operators. The purposed genetic operators have enhanced the performance of the process scheduling. The proposed BQPSGA is shown in fig.1.

Fig.1.Proposed BQPSGA for OSPSP

### 5.1 Selection Operator

The performance of the GA is greatly depends upon the Selection operator. Selection operator chooses the fittest individual solution for reproduction. In the present work, "Modified Random Selection (MRS)" operator is proposed.

### 5.2 Crossover Operator

Rajiv et.al. [7] has been proposed ten new crossover operators. These operators are based on permutation encoding. The list of the proposed crossover operators are:

1. Modified Maximal Preservative Right Side Placement Crossover (MMPX) Operator
2. Sorted Partially Matched With Same Position Crossover(SPMX-1) Operator
3. Sorted Partially Matched Right Side Placement Crossover (SPMX-2) Operator
4. Random Order with Random Sequence Placement Crossover (RORPX) Operator
5. Random Select with Left shift Placement Crossover (RLSX) Operator
6. Random Select with Right Shift Placement Crossover (RRSX) Operator
7. Sub Schedule Match Crossover (SSMX-1) Operator
8. Sub Schedule Match Crossover with Reverse Placement (SSMX-2) Operator
9. Sub Schedule Match Inverted Crossover (SSMIX-1) Operator
10. Sub Schedule Match Inverted Crossover (SSMIX-2) Operator

### 5.3 Mutation Operator

Rajiv et.al.[7] has proposed "Selective Swap Mutation (SSM)". The main assumption used here is that sometime due to after much generation, the best genes in the chromosome reach at the extreme position in the chromosome. The extreme positions are the first and last. When the extreme positions of genes are exchanged, then there is tendency to backtrack or to find out the optimal solution.

## 6 Experimental Setup

To solve the scheduling problem various new operators have been developed by the author. GAPS simulator have been developed [7].GAPSS provide the environment in which different types of operators have been studied. This simulator is designed in C Language.

## 7.Simulation Result and conclusion

The simulation results show that the proposed genetic operators to solve the OSPSP are efficient. The results are shown in Table No.1.,Table No. 2 and Fig. 2,3,4,5 They shows better result as compared to the existing operators. BQPSGA is a new algorithm which can be used as long term scheduler in the operating system.GA cannot be used as short term scheduler because it takes lot of time to produce the result. In case of batch system GA will be applicable.
