

DBMS AS A CLOUD SERVICE

Seenu Garg

Abstract – Recently technological advancement, especially those of the cloud services have reached a high point of development and research. However, the technology and principles change rapidly and there is an increasing number of open problems. Nowadays, DBMS outsourcing is one of the most required features of cloud services. Technological advancements around transmission of data through the network, have largely influenced the cost of transmitting the data per terabyte over long distances. This new outsourcing model has the benefits of reducing the cost for running Database Management System (DBMS) independently.

Keywords: SQL (Structured Query Language), RDBMS (Relational Database Management System), BigData, IaaS (Infrastructure as a service), PaaS (Platform as a service)

I. INTRODUCTION

A Cloud database management system is a distributed database that delivers computing as a service instead of a product. It is the sharing of resources, software, and information between multiple devices over a network which is mostly the internet. It is expected that this number will grow significantly in the future. As a result, there is a growing interest in outsourcing database management tasks to third parties that can provide these tasks for much lower cost due to the economy of scale just like putting it into the cloud. In this paper, we discuss the recent trend in database management system and the possibilities of making it as one of the services offered in the cloud.

II. Cloud Characteristics

One of the oft-cited advantages of cloud computing is its elasticity in the face of changing conditions. For example, during seasonal or unexpected spikes in demand for a product retailed by an e-commerce company, or during an exponential growth phase for a social networking Website, additional computational resources can be allocated on the fly to handle the increased demand in mere minutes (instead of the many days it can take to procure the space and capital equipment needed to expand the computational resources in-house). Using Database as a Cloud Service allows the user to access the data stored on an online database (present on a cloud) and is hence proving to be an efficient technological advancement these days.

III. DBMS AS A CLOUD SERVICE

Most DBMS or database management systems are simply software packages that users can acquire to create, maintain or use a database. However, since the introduction of cloud computing, DBMS has morphed into an entirely new type of service with its own unique benefits and task specific advantages. For one thing, any type of cloud service model will have to employ a dedicated cloud DBMS in order to truly provide customers with excellent access to data and databases. Traditional DBMS's are simply not set up or equipped to deal with the demands of cloud computing. And of course, if DBMS was deployed as a service as part of a

larger package provided, it would likely be much more efficient in its duties and therefore cheaper in the long run.

The concept of the DBMS has been around since the beginning of commercial computing; such as the navigational DBMS of the 1960's. Database management systems are one of the oldest integral components of computing, essentially making it possible to scan, retrieve and organize data on hard drives and networks. All DBMS, despite whether traditional or cloud-based, are essentially communicators that function as middlemen between the operating system and the database.

How is a cloud DBMS different a traditional one? For one thing, cloud-based DBMS are extremely scalable. They are able to handle volumes of data and processes that would exhaust a typical DBMS. Despite their scalability however, cloud DBMS are still somewhat lacking in their ability to scale up to extremely large processes; this is expected to be remedied in the coming months and years however. Currently, the use of cloud DBMS's are principally used in the testing and development of new cloud applications and processes. But while a stand-alone DBMS can be used on a cloud infrastructure; most are not designed to take full advantage of cloud resources. DBMS as a cloud service-type models seek to capitalize on the disparity between antiquated DBMS models and their lack of full cloud functionality.

IV. CLOUD DATABASE STRATEGY

The cloud database strategy decide upon the assumption that how database support will be offered in the cloud. The wrong cloud database strategy can create application performance problems significant enough to discredit a cloud service, forcing the provider to incur additional costs to establish credibility with users.

The cloud database issue is complicated because it sits at the intersection of two cloud infrastructure models, two storage service models and two database management systems (DBMS) models. Public cloud-based databases can offer more sophisticated security models and mechanisms, as well as data-level governance to set policies around the use of data.

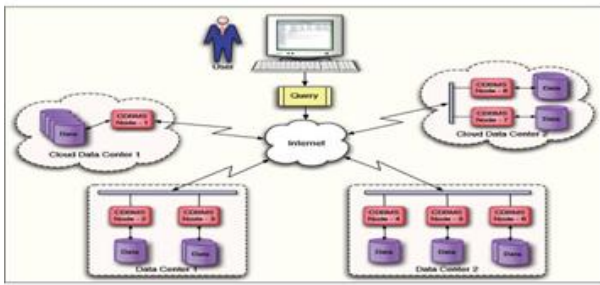

Fig. 1 Basic model of Cloud Database

The following services models can affect cloud database support:

1) *Single and multi-site cloud models:* It differs in the way that resources are allocated to customers. In the single-site model, a customer’s applications run within a single data centre in the cloud, even if multiple data centres are available. In this single site model storage of a customer can be contained within a single storage area network (SAN), and that the customer’s application performance in the cloud can likely match that of a standard data centre that uses virtualization. In the multi-site model, the customer’s applications can draw on resources from multiple data centres, which mean that making the connection between the application and the database resources could involve WAN connectivity that limits performance. Depend on their choices, service providers must be ready to address the issues that come with single- or multi-site cloud infrastructure.

2) *Storage models:* The storage service models available to a cloud planner are Storage as a Service or the more complex Database as a Service. With storage services, the customer will access virtual storage devices as though they were native disk arrays, which means that the applications will send storage protocols (such as Fibre Channel over Ethernet or IP SCSI) over any network connection. In the relatively new Database as Service offerings, applications will access storage through a cloud DBMS that will accept high-level database commands and return the required results. This can create a less delay-sensitive connection, so it is better suited to cloud configurations where storage might be distributed over multiple sites.

Another major cloud database planning decision is whether a cloud database service should be based on the popular relational database management system (RDBMS) and its Structured Query Language (SQL) standards, based on a lighter-weight RDBMS without SQL, or based on a non-relational structure like the ‘Google BigTable’ structure that gives users dynamic control over data layout and format.

V. DBMS IN CLOUD ARCHITECTURE

Above is a proposed DBMS in Cloud Architecture, first layer is the storage, followed by databases and the upper layer is application layer. In terms of performance, it provides efficient data access with a better distribution of values for some data. Stores frequently used SQL statements in memory, avoiding the need for time-consuming recompilation at run-time. Produces a detailed report on each

step used for data access, allowing you to accurately implement performance enhancements. Data is encrypted when stored or backed up, without any need for programming to encrypt and decrypt.

Fig 2. DBMS in Cloud Architecture

VI. THE VALUE OF DBMS AS A CLOUD SERVICE

A. Advantages:

1. Parallelization of computer workload. Parallel computing reaches to solve the problem by scheduling tasks.
2. With a direct storage model, a mechanism for storage virtualization that protects customers’ data from being accessed by others but still makes the virtual disks look “real” is essential
3. In cloud platform shared memory is an architecture which allows multiple CPUs to access on it for the only intent to provide communication between them, or to eliminate redundant copies.
4. It’s easy to provide cloud database services as part of a cloud Platform as a Service (PaaS) offering, but the applications may have to be written to access cloud database services in some Infrastructure as a Service (IaaS) configurations.
5. Offering Database as a Service can help by replacing storage input/output (I/O) with simply sending a query and a return of results.

B. Disadvantages :

- 1) If customers are likely to access the storage/DBMS across multiple data centres in cloud, the performance implications may be critical.
- 2) Privacy has been the most important issue when it comes to cloud computing. The companies cannot afford to leak out information that is stored in their database. If there is encryption of data in the database, then it is quite easy to store it in an easy way.

- 3) *Query and Transactional workload:* Transactional workload determines the overall time that will be required. While we are able to control the transactions we are not able to control query workload, because it depends on the number of queries and we don't know the number of the users that are waiting to execute queries.
- 4) *Multi tenancy:* Multi-tenancy is when a single software instance serves hundred users at the same time. In addition cloud providers always think that increasing the number of machines will affect in providing better results but increasing the number of machines it is not always the best solution, because growing the number of machines affects in efficiency of database.

VII. CONCLUSIONS

In this paper, we review database management systems offered as services in cloud platforms. We started with current achievements of cloud databases, continuing with three main characteristics which helps the users to clarify the idea of moving from traditional DBMS to a cloud DBMS, suggesting to readers to migrate to the cloud.. In this paper, we read the possibilities to be offered as one of the services offered by promising capability of cloud computing, that is to be a DBMS as a Service. In this paper we proposed architecture of DBMS in the cloud.
